

Projektowanie złożonych systemów telekomunikacyjnych

Biblioteka standardowa

Łukasz Marchewka

Agenda:

- Memory management
 - Leaks
 - RAI
 - Smart pointers: `std::unique_ptr`, `std::shared_ptr`, `std::weak_ptr`
- STL – Standard Template Library
 - Containers:
 - Sequence containers: **`std::array`**, **`std::vector`**, **`std::list`** (`std::forward_list`), **`std::deque`**
 - Associative containers: **`std::set`**, **`std::map`** (`std::multimap`)
 - Containers adapters: **`std::queue`**, **`std::priority_queue`**, **`std::stack`**
 - **`std::tuple`**
 - Iterators

C++ History

- Started in 1979 as '**C with Classes**' by Bjarne Stroustrup
- 1983 – renamed as the **C++** (C incremented)
- 1994 – first appearance of the **STL** (A. Stepanov), HP implementation
- ISO standards (ISO/IEC 14882)
 - 1998 – first ISO standard (**C++98**)
 - 2003 – minor corrections (**C++03**)
 - 2007 – Technical Report 1, additions to std. library (**C++TR1**)
 - 2011 – major revision of language (**C++11**, former *C++0x*)
 - 2014 – minor improvements (**C++14**)
 - 2017 – several improvements (**C++17**)
 - 2020 – next standardization (**C++20**)

New features since C++03

- ***performance:*** r-value references, move semantic, constant expressions, data alignment, unions
- ***less errors:*** nullptr, override, final, default, deleted, static asserts, explicit conversion, enumerations, loops, exceptions, integral types
- ***automatic memory management:*** smart pointers, STL allocators
- ***concurrency support:*** memory model, kinds of variables, thread creation and synchronization, tasks
- ***metaprogramming:*** auto, decltype, variadic templates, right angle bracket bug, template aliases, type traits
- ***functional programming:*** callable objects, lambda expressions, functional types, binding
- ***strings and characters:*** unicode, new character types, new string literals
- ***data initialization:*** initializer lists, member initialization, constructors, user defined literals
- ***new STL stuff:*** tuples, containers, regular expressions, random number generation, rational numbers, timers

Memory Management

Memory Leaks

- Memory leak occurs when the memory is allocated by using "new" keyword and is not deallocated by using delete() function or delete[].
- A program with memory leaks is satirically increasing memory usage of a system and all systems have limited amount of memory.
- Even if a program is written correctly a memory leak can occur caused by an exception

```
#include <iostream>

void memoryLeak()
{
    int* ptr = new int(5);
    return;
}

int main()
{
    memoryLeak();
    return 0;
}
```

Memory Leaks

- Use smart pointers as often as possible, instead of managing memory manually (raw pointers)
 - Use `std::make_unique` and `std::make_shared` functions to create intelligent pointers smart pointers
- Use [`std::string`](#) instead of `char *`. The `std::string` class handles all memory management internally, is fast and well-optimized.
- Never use a raw pointer (exception: an interface to an older library)
- Keep as few `new/delete` calls at the program level as possible – ideally NONE.
- Allocate memory by „new” keyword and deallocate memory by „delete” keyword and write all code between them.
- If you use local pointer in member function (which is not an attribute of current class), it is highly probable that local variable is good enough
- Apply RAI pattern

Memory Leaks

```
int main()
{
    int tab[100];
    tab[100] = 10;
    return 0;
}
```

```
int main()
{
    int* p = new int[10];
    p[10] = 10;
    int a = p[10];
    return 0;
}
```

```
int main()
{
    int* p = new int[10];
    delete [] p;
    p[2] = 10;
    return 0;
}
```

```
int main()
{
    int x;
    if (x == 10)
    {
        x = 20;
    }
    return 0;
}
```

RAII - Resource Acquisition is Initialisation

- The resource is acquired in the constructor
- The resource is released in the destructor (e.g. closing a file, deallocating a memory)
- Instances of the class are stack allocated
- If an object requires dynamic memory it should allocate a memory in a constructor and release in a destructor -> it is a guarantee that a memory is deallocated when a variable leaves the current scope
- **C++ guarantees that the destructors of objects on the stack will be called, even if an exception is thrown**

RAII - Resource Acquisition is Initialisation

- Find a bug
- Apply RAII pattern

```
#include <iostream>

struct A
{
    int m_name{0};
    A(int p_name) : m_name(p_name) { std::cout << "A(" << m_name << ") constructed successfully\n"; }
    ~A() { std::cout << "A(" << m_name << ") destroyed\n"; }
};

struct B
{
    A* a1 = new A{5};
    B() { std::cout << "B constructed successfully\n"; }
    ~B() { std::cout << "B destroyed\n"; }
};

int main()
{
    B b{};
    return 0;
}
```

RAII - Resource Acquisition is Initialisation

```
struct A
{
    A() : { std::cout << "A constructed successfully\n"; }
    ~A() { std::cout << "A destroyed\n"; }
};

struct B
{
    A* a1 = new A{5};
    B() { std::cout << "B constructed successfully\n"; }
    ~B() { std::cout << "B destroyed\n"; }
};

int main()
{
    B b{};
    return 0;
}

struct BRaii\\\
{
    A* a1;
    BRaii() {
        a1 = new A{};
        std::cout << "BRaii constructed successfully\n";
    }

    ~BRaii() {
        delete a1;
        std::cout << "BRaii destroyed\n";
    }
};
```

Smart pointers: `unique_ptr` and `shared_ptr`, `weak_ptr`

- The C++11 standard introduces new type of pointers for avoiding memory leaks. Pointers known from previous standards (with asterisk: i.e. `int* ptr`) of C++ are called raw pointers.

Unique pointers

- The `std::unique_ptr` is a kind of smart pointer which eliminates the risk of resource leaks
- Unique pointers have ownership of the internal objects
 - no more than one unique pointer can own the same object
 - destructors of unique pointers automatically destroy owned objects
- Unique pointers replace auto pointers from C++03
 - unique pointers support only move semantic
 - unique pointers properly support arrays and allow replacing the default `delete` and `delete[]` operators used to release owned objects
 - (auto pointers support only copy semantic, but actually perform move (!))

The `std::auto_ptr` is deprecated now, do not use it!

Unique pointers

- The example use cases of unique pointers:
 - `std::unique_ptr<int> ptr1(std::make_unique(13));`
`std::unique_ptr<int[]> ptrToArray(std::make_unique<int[]>(5));`
`std::unique_ptr<int> ptr2 = ptr1; // compile error,`
`std::unique_ptr<int> ptr3 = std::move(ptr1); // OK`
`ptr1.reset(); // OK, but no effect`
`ptr3.reset(); // Forces to destroy object`
 - `std::unique_ptr<float> func() {...} // OK, fine with`
`std::unique_ptr<float> rslt = func(); // move semantic`
- The function `std::make_unique` is available since C++14
 - `int* ptr1 = new int(5);`
`std::unique_ptr<int> ptr2(ptr1); // compiles OK,`
`std::unique_ptr<int> ptr3(ptr1); // but serious error`

function `std::make_unique` assures that this kind of errors is impossible

Shared pointers

- Shared ownership for dynamically created object
- Keeps internal number of references to the object -> copy of `shared_ptr` increments that number
- Number of `shared_ptr` controlling one object is not changed by move operation. Just the pointer is set to `nullptr`, however it is faster than standard copy
- Shared pointers provide automatic memory management using reference counting
 - attaching a shared pointer increments reference counter
 - destroying a shared pointer decrements the counter, freeing the object if and only if the counter drops to zero
- Performance penalty: heap fragmentation and two actual memory dereferences performed by dereference operators
- Not foolproof – objects in circular references would never be destroyed

Shared pointers

- use_count() -> displays how many the shared pointers point the resource

```
#include <iostream>
#include <memory>

struct A
{
    int m_name{0};
    A(int p_name) : m_name(p_name) { std::cout << "A(" << m_name << ") constructed successfully\n"; }
    ~A() { std::cout << "A(" << m_name << ") destroyed\n"; }
    void getName() { std::cout << __FUNCTION__ << ": A(" << m_name << ")\n"; }
};

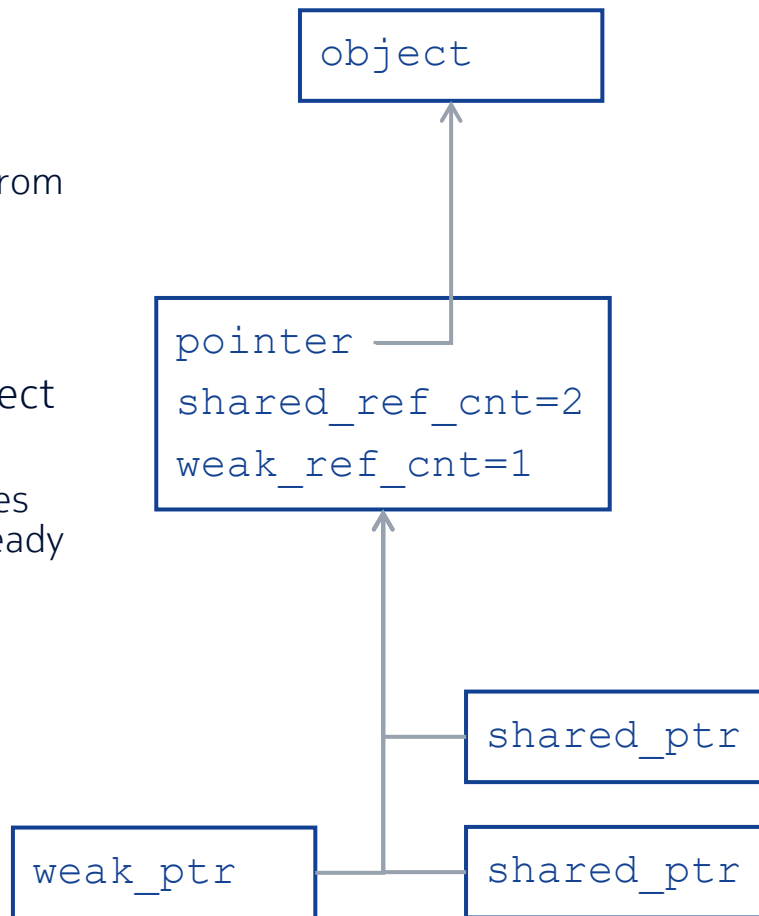

void foo(std::shared_ptr<A> p_ptr)
{
    p_ptr->getName();
    std::cout << "Function End\n";
}

int main()
{
    std::shared_ptr<A> ptr1(std::make_shared<A>(13));
    foo(ptr1);

    std::cout << "PROGRAM END\n";
}
```

Shared and weak pointers

- Weak pointers can be used to break circular references
 - any shared pointer pointing to an object prevents from deleting it
 - weak pointers do not prevent from deleting object
- Weak pointers can be queried if the pointed object still exists
 - careful usage of shared and weak pointers eliminates the possibilities of double-delete and access to already deleted objects

Weak pointers

- Weak pointers have two functions for querying object existence
 - `shared_ptr<T> lock() const;`
returns either a shared pointer to the object if it still exists or null pointer otherwise
 - `bool expired() const;`
verifies if weak pointer still points to an object
- The example use cases of shared and weak pointers:

```
std::shared_ptr<int> ptr1(std::make_shared<int>(13));  
std::shared_ptr<int> ptr2(ptr1); // refcnt=2  
std::weak_ptr<int> wptr(ptr1);   // still refcnt=2  
ptr1.reset(); // refcnt=1, no delete  
{ wptr.lock(); } // returns a non-null shared pointer  
ptr2.reset(); // refcnt=0, deletes object  
{ wptr.lock(); } // now returns a null shared pointer
```

STL – Standard Template Library

- The Standard Template Library defines template-based, reusable components that implements common data structures and algorithms
- STL extensively uses generic programming based on templates
- Divided into components:
 - Containers: data structures that store objects of any type
 - Iterators: used to manipulate container elements
 - Algorithms: searching, sorting and many others
 - Functors: objects that behave like functions/functions pointers (define operator()), but can hold a state

STL – Containers

- Is a data structure that can store objects of any type with a defined interface (<https://en.cppreference.com/w/cpp/container>)
- Container manages memory, which is needed to store its elements

Containers

- Three types of containers
 - Sequence containers:
 - linear and ordered data structures, each element has a position that depends on time and place of the insertion. Examples: vectors and linked lists
 - Associative containers:
 - non-linear and sorted data structures, position of an element depends on value. Example: sets and maps
 - Container adapters:
 - constrained sequence containers such as stacks and queues
- Sequence and associative containers are also called first-class containers

Sequence Containers

- STL provides sequence containers as follows:
 - `std::array`
 - `std::vector`: based on arrays
 - `std::deque` (double-ended queue): based on arrays
 - `std::list`
 - `std::forward_list`

Array - `template<class T, size_t N> class array;`

- Public methods related to capacity:
 - `size`
 - `empty`
 - `max_size`
- Other methods:
 - `fill`
 - `swap`
- In case of array we can use comparison operators.

Array - `template<class T, size_t N> class array;`

- Array – fixed size container similar to vector
 - Zero overhead over classic C array []
 - Just member functions that make C array compatible with STL containers and tuples
 - Does not keep any data other than elements it contains (not even size)
 - Element can be reached by operator []
 - Random access in constant time $O(1)$

Array - template<class T, size_t N> class array;

- Examples

```
#include <iostream>
#include <array>

int main()
{
    std::array<int, 3> arr1 = {1, 2, 3};
    std::array arr2 = {1, 2, 3}; // introduced in C++17

    arr1[0] = arr2[2] = 8;

    std::cout << "Count: " << arr1.size() << ", " << arr2.size() << std::endl;

    for(int it : arr1)
    {
        std::cout << it << " ";
    }

    std::cout << std::endl;
    auto [v1, v2, v3] = arr2; // introduced in C++17
    std::cout << v1 << " " << v2 << " " << v3;
}
```

Array - template<class T, size_t N> class array;

- Examples

```
std::array<int, 5> numbers;  
  
std::cout << std::boolalpha;  
std::cout << "Is empty: " << numbers.empty() << '\n';  
std::cout << "Size: " << numbers.size() << '\n';  
std::cout << "Max size: " << numbers.max_size();
```

```
Is array empty: false  
Numbers in array: 5  
Max size: 5
```

Array - template<class T, size_t N> class array;

- Examples

```
std::array<int, 3> arr1 = {1, 2, 3};
std::array arr2 = {3, 3, 3}; // C++17
std::cout << "Arr1: ";
printArray(arr1);
std::cout << "Arr2: ";
printArray(arr2);

arr1.swap(arr2);
std::cout << "Arr1: ";
printArray(arr1);
arr1[0] = arr2[1] = 5;

std::cout << "Count: " << arr1.size() << ", " << arr2.size() <<
std::endl;
std::cout << "Arr1: ";
printArray(arr1);
```

```
Arr1: 1 2 3
Arr2: 3 3 3
Arr1: 3 3 3
Count: 3,3
Arr1: 5 3 3
```

```
std::array<int, 3> numbers;
numbers.fill(7);

std::printf(„Numbers:\n");
printArray(numbers);
```

```
Numbers:
7 7 7
```

Array - template<class T, size_t N> class array;

- Examples

```
namespace LegacyCode
{
    void printArr(int* p_arr, size_t p_size)
    {
        std::cout << "Printing Legacy Array: ";
        for (int* it = p_arr; it != p_arr + p_size; ++it)
            std::cout << *it << " ";
        std::cout << '\n';
    }
}

int main()
{
    std::array arr = { 1, 2, 3, 4, 5 };
    LegacyCode::printArr(arr.data(), arr.size());
}
```

Printing Legacy Array: 1 2 3 4 5

Array - `template<class T, size_t N> class array;`

API	Description
<code>at(int index)</code>	This returns the value stored at the position referred to by the index. The index is a zero-based index. This API will throw an <code>std::out_of_range</code> exception if the index is outside the index range of the array.
<code>operator [int index]</code>	This is an unsafe method, as it won't throw any exception if the index falls outside the valid range of the array. This tends to be slightly faster than <code>at</code> , as this API doesn't perform bounds checking.
<code>front()</code>	This returns the first element in the array.
<code>back()</code>	This returns the last element in the array.
<code>begin()</code>	This returns the position of the first element in the array
<code>end()</code>	This returns one position past the last element in the array
<code>rbegin()</code>	This returns the reverse beginning position, that is, it returns the position of the last element in the array
<code>rend()</code>	This returns the reverse end position, that is, it returns one position before the first element in the array
<code>size()</code>	This returns the size of the array

- Source: <https://subscription.packtpub.com/>

Vector - `std::vector<T, Alloc = std::allocator<T>>`

- The implementation of a vector is based on arrays, it encapsulates dynamic size array
- Vectors allow direct access to any element via indexes $O(1)$
- Insertion at the end is normally efficient, the vector simply grows
- Insertion and deletion in the middle is expensive, an entire portion of the vector needs to be moved
- First choice for data structure in C++

```
template <class T, class Allocator = std::allocator<T>>  
class vector;
```

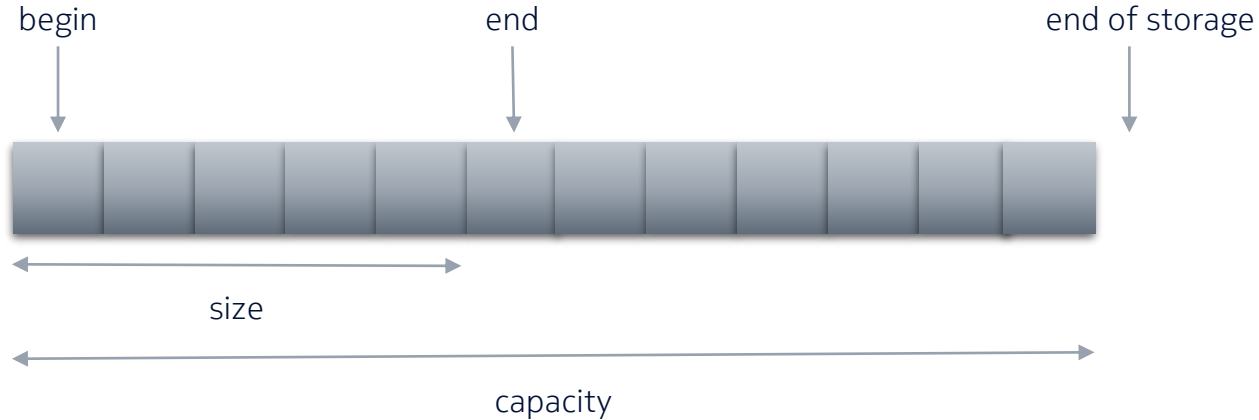

```
// e.g.  
std::vector<int> integers;  
std::vector<double> rationals;  
std::vector<std::string> surnames;
```

Vector - `std::vector<T, Alloc = std::allocator<T>>`

- Elements are stored contiguously, can be accessed by regular pointers to elements
- Uses more memory to handle future growth
- When the vector capacity is reached then
 - A larger vector is allocated
 - The elements of the previous vector are copied and
 - The old vector is deallocated
- Some functions: `size`, `capacity`, `insert`, `push_back`, `erase`
 - `data()` – returns pointer to array containing all vector elements, similar to `&vec.first()`, but safe on empty vectors
 - `shrink_to_fit()` – reduces pre-allocated memory to be not much larger than necessary to contain all elements, it is a hint only!

Vector - `std::vector<T, Alloc = std::allocator<T>>`

- How vector can look:

Vector - `std::vector<T, Alloc = std::allocator<T>>`

- How to access elements:
 - `at / operator[]`
 - `front / back`
 - `data`
 - Using iterators:
 - `begin / cbegin`
 - `end / cend`
 - `rbegin / crbegin`
 - `rend / crend`
- `std::vector::iterator` is a random-access iterator

API	Description
<code>at (int index)</code>	This returns the value stored at the indexed position. It throws the <code>std::out_of_range</code> exception if the index is invalid.
<code>operator [int index]</code>	This returns the value stored at the indexed position. It is faster than <code>at(int index)</code> , since no bounds checking is performed by this function.
<code>front()</code>	This returns the first value stored in the vector.
<code>back()</code>	This returns the last value stored in the vector.
<code>empty()</code>	This returns true if the vector is empty, and false otherwise.
<code>size()</code>	This returns the number of values stored in the vector.
<code>reserve(int size)</code>	This reserves the initial size of the vector. When the vector size has reached its capacity, an attempt to insert new values requires vector resizing. This makes the insertion consume O(N) runtime complexity. The <code>reserve()</code> method is a workaround for the issue described.
<code>capacity()</code>	This returns the total capacity of the vector, while the size is the actual value stored in the vector.
<code>clear()</code>	This clears all the values.
<code>push_back(data_type value)</code>	This adds a new value at the end of the vector.

Vector - `std::vector<T, Alloc = std::allocator<T>>`

- Public methods related to capacity:
 - `size`
 - `empty`
 - `capacity`
 - `reserve`
 - `shrink_to_fit`
 - `max_size`

Vector - std::vector<T, Alloc = std::allocator<T>>

- Examples:

```
std::vector<int> vec1;  
std::vector<int> vec2 { 1, 2, 3 };  
std::cout << "Vec1: Number of elements: " << vec1.size() << std::endl;  
std::cout << "Vec1: capacity: " << vec1.capacity() << std::endl;
```

```
vec1.push_back(3);  
vec1.push_back(1);  
vec1.push_back(2);
```

```
std::cout << "Vec1: Number of elements: " << vec1.size() << std::endl;  
std::cout << "Vec1: capacity: " << vec1.capacity() << std::endl;
```

```
std::cout << "Vec1: ";  
printVector(vec1);  
std::cout << "Vec2: ";  
printVector(vec2);
```

```
Vec1: Number of elements: 0  
Vec1: capacity: 0  
Vec1: Number of elements: 3  
Vec1: capacity: 4  
Vec1: 3 1 2  
Vec2: 1 2 3
```

Vector - `std::vector<T, Alloc = std::allocator<T>>`

- Examples:

```
std::vector<int> primes {2, 3, 5, 7, 11};
```

```
int product = 1;
for (size_t i = 0; i < primes.size(); ++i)
{
    product *= primes.at(i);
}
std::cout << "Product: " << product;
```

Product: 2310

```
int sum = 0;
for (size_t i = 0; i < primes.size(); ++i)
{
    sum += primes[i];
}
std::cout << "Sum: " << sum << '\n';
```

Sum: 28

Vector - `std::vector<T, Alloc = std::allocator<T>>`

- Examples:

```
std::vector<int> primes {2, 3, 5, 7, 11};
```

```
std::cout << "Front: " << primes.front() << '\n';  
std::cout << "Back:  " << primes.back() << '\n';
```

```
Front: 2  
Back: 11
```

Vector - `std::vector<T, Alloc = std::allocator<T>>`

- Examples:

```
void some_c_api_function(int* someArrayPtr, size_t size)
{
    // some low-level stuff
}

int main(int argc, char** argv)
{
    std::vector<int> primes {2, 3, 5, 7, 11};
    some_c_api_function(primes.data(), primes.size());
    return 0;
}
```

Vector - `std::vector<T, Alloc = std::allocator<T>>`

- Examples:

```
std::vector<int> primes {2, 3, 5, 7, 11};
```

```
template <typename ForwardIterator>
void displayRange(ForwardIterator first, ForwardIterator last)
{
    while (first != last) {
        std::cout << *first++ << ", ";
    }
}
```

```
displayRange(primes.rbegin(), primes.rend());
```

11, 7, 5, 3, 2,

```
displayRange(primes.begin(), primes.end());
```

2, 3, 5, 7, 11,

Vector - `std::vector<T, Alloc = std::allocator<T>>`

- `std::vector<bool>` is optimized in case of needed memory
- Does not necessarily store its elements as a contiguous array
- To access elements it returns proxy objects
 - Additional methods: `flip`, `swap`

```
std::vector<bool> v {true, false};
```

```
auto& firstElementRef = v.front(); // Compilation error!
```

```
auto firstElementProxy = v.front(); // Proxy object
```

Vector - std::vector<T, Alloc = std::allocator<T>>

Custom Allocator:

```
#include <iostream>
#include <vector>

template <class T>
class MyAlloc
{
public:
    using value_type = T;

    MyAlloc(std::string name = "Test myAlloc", int allocs = 0) : m_name(name), m_allocs(allocs)
    {
        std::cout << "Allocator " << m_name << " constructor" << std::endl;
    }

    T* allocate(std::size_t n)
    {
        m_allocs++;
        std::cout << "Allocator " << m_name << " allocation number: " << m_allocs << std::endl;
        return std::allocator<T>().allocate(n);
    }

    void deallocate(T *ptr, std::size_t n)
    {
        std::cout << "Allocator " << m_name << " deallocation" << std::endl;
        std::allocator<T>().deallocate(ptr, n);
    }

    using propagate_on_container_copy_assignment = std::true_type;
    using propagate_on_container_move_assignment = std::true_type;
    using propagate_on_container_swap = std::true_type;

    std::string m_name;
    int m_allocs;
};

template <typename T, typename U>
bool operator==(const MyAlloc<T>&a, const MyAlloc<U>&b)
{
    std::cout << "operator==" << std::endl;
    return a.m_name == b.m_name;
}

template <typename T, typename U>
bool operator!=(const MyAlloc<T>&a, const MyAlloc<U>&b)
{
    return !(a == b);
}
```

```
int main()
{
    std::cout << "=====1======" << std::endl;
    std::vector<int, MyAlloc<int>> test1(MyAlloc<int> ("First"));
    test1.push_back(11);

    std::cout << "=====2======" << std::endl;
    std::vector<int, MyAlloc<int>> test2(MyAlloc<int> ("Second"));
    test2.push_back(22);

    std::cout << "=====3======" << std::endl;
    std::vector<int, MyAlloc<int>> test3;
    test3.push_back(33);

    std::cout << "=====4======" << std::endl;
    std::vector<int, MyAlloc<int>> test4;
    test4.push_back(44);

    std::cout << "=====POCCA======" << std::endl;
    test3 = test1;
    test3.push_back(10);

    std::cout << "=====POCMA======" << std::endl;
    test4 = move(test2);
    test4.push_back(10);
}
```

List - `std::list <T, Alloc = std::allocator<T>>`

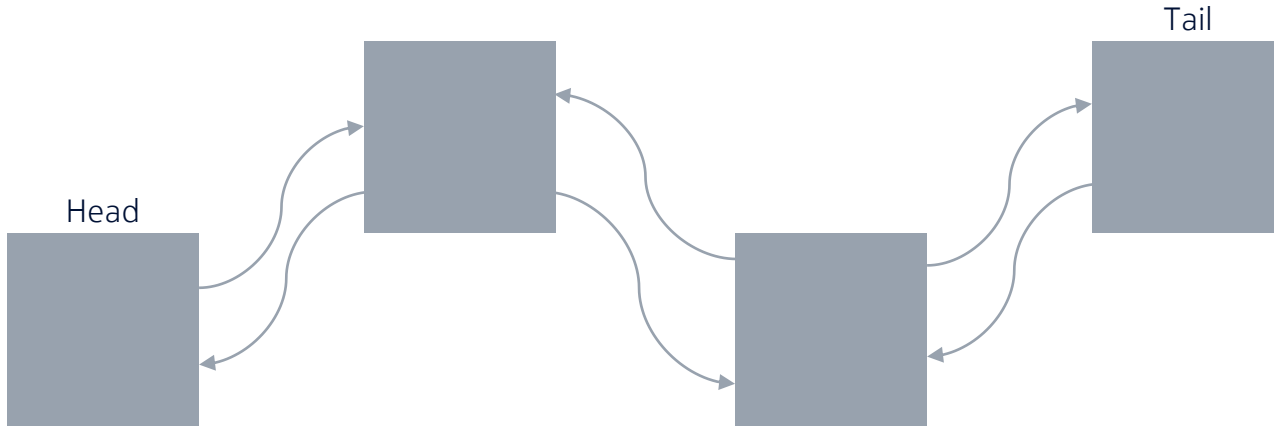

- List is implemented using a doubly-linked list
- Each element contains pointers to previous and next element.
- Random access is not supported, you have to iterate to the specific position
- Insertions and deletions are efficient (constant time) at any point of the list
 - But you have to have access to an element in the middle of the list first
- Bidirectional iterators are used to traverse the container in both directions
- May lead to memory fragmentation

```
template <class T, class Allocator = std::allocator<T>>  
class list;
```

```
// e.g.  
std::list<int> integers;  
std::list<std::string> surnames;
```

List - `std::list <T, Alloc = std::allocator<T>>`

- How doubly-linked list can look.

List - `std::list <T, Alloc = std::allocator<T>>`

- How to access elements:

- `front` / `back`
- Using iterators:
 - `begin` / `cbegin`
 - `end` / `cend`
 - `rbegin` / `crbegin`
 - `rend` / `crend`

API	Description
<code>front()</code>	This returns the first value stored in the list
<code>back()</code>	This returns the last value stored in the list
<code>size()</code>	This returns the count of values stored in the list
<code>empty()</code>	This returns <code>true</code> when the list is empty, and <code>false</code> otherwise
<code>clear()</code>	This clears all the values stored in the list
<code>push_back<data_type>(value)</code>	This adds a value at the end of the list
<code>push_front<data_type>(value)</code>	This adds a value at the front of the list
<code>merge(list)</code>	This merges two sorted lists with values of the same type
<code>reverse()</code>	This reverses the list
<code>unique()</code>	This removes duplicate values from the list
<code>sort()</code>	This sorts the values stored in a list

- `std::list::iterator` is a bidirectional iterator

- Source: <https://subscription.packtpub.com/>

List - `std::list <T, Alloc = std::allocator<T>>`

- How to modify list:
 - `push_back` / `push_front`
 - `pop_back` / `pop_front`
 - `emplace_back` / `emplace_front`
 - `insert` / `emplace`
 - `erase`
 - `clear`
 - `resize`
 - `swap`

List - `std::list <T, Alloc = std::allocator<T>>`

- Special operations of `std::list`:
 - `sort`
 - `merge`
 - `splice`
 - `reverse`
 - `unique`
 - `remove / remove_if`

List - `std::list <T, Alloc = std::allocator<T>>`

- Examples:

```
std::list<int> l_list;  
l_list.push_back(3);  
l_list.push_back(2);  
l_list.push_back(1);  
std::cout << "Number of elements: " << l_list.size() << std::endl;  
  
printList(l_list);  
  
auto it = std::find(l_list.begin(), l_list.end(), 2);  
if (it != l_list.end())  
{  
    l_list.insert(it, 4);  
}  
  
printList(l_list);
```

```
Number of elements: 3  
3 2 1  
3 4 2 1
```

Forward lists

- Singly-linked list
- Zero space or time overhead relative to a hand-written C-style singly linked list
- Random access is not supported
- May lead to memory fragmentation
- Fast insert/remove operations
- Uses less memory than `std::list`, but can be traversed only in one direction, support only forward iterators, no bidirectional and reverse ones

```
template <class T, class Allocator = std::allocator<T>>  
class forward_list;
```

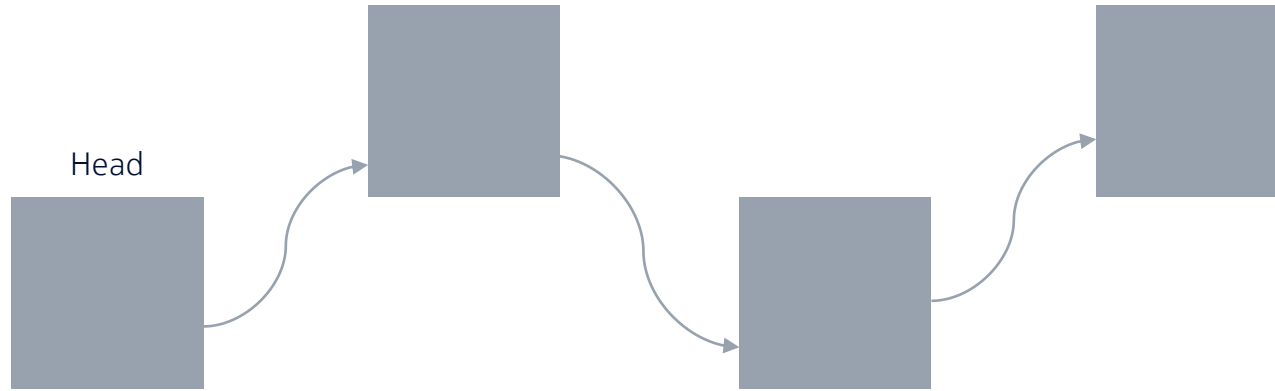

```
// e.g.  
std::forward_list<int> integers;
```

Forward lists

- no `size()` member function
- pointer to the last element is not stored – no `back()`, `push_back()` and `pop_back()` member functions
- `insert_after()`, `erase_after()` and `splice_after()` instead of respective methods of `std::list`
- additional iterator position – `before_begin()`

Forward lists

- How singly-linked list can look

Forward lists

- How to access elements:
 - `front`
 - Using iterators:
 - `begin / cbegin`
 - `end / cend`
 - `before_begin, cbefore_begin`
- `std::forward_list::iterator` is a forward iterator

Forward lists

- How to modify forward_list:
 - push_front / emplace_front / pop_front
 - insert_after / emplace_after
 - clear
 - erase_after
 - swap
 - resize

Forward lists

- Special operations of forward_list:
 - sort
 - merge
 - reverse
 - splice_after
 - unique
 - remove / remove_if

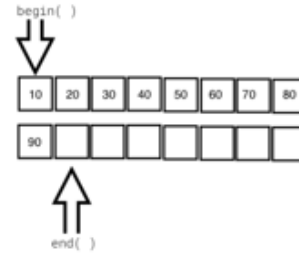

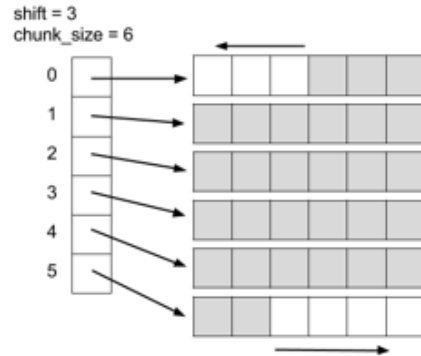

Deque - `std::deque<T, Alloc = std::allocator<T>>`

- Double-ended queue – often implemented as many chunks of memory, which are allocated independently (elements are not stored contiguously)
- In case of being full, it reallocates memory
- Supports random access
- Fast insert/remove operations at the beginning/end.

Deque - `std::deque<T, Alloc = std::allocator<T>>`

- Deque combines the benefits of vector and list
- It provides indexed access using indexes (which is not possible using lists)
- It also provides efficient insertion and deletion in the front (which is not efficient using vectors) and the end
- Additional storage is allocated using blocks of memory, that are maintained as an array of pointers to those blocks
- Same functions as for vector

Deque - `std::deque<T, Alloc = std::allocator<T>>`

Deque - `std::deque<T, Alloc = std::allocator<T>>`

- How to access elements:
 - `at` / `operator[]`
 - `front` / `back`
 - Using iterators:
 - `begin` / `cbegin`
 - `end` / `cend`
 - `rbegin` / `crbegin`
 - `rend` / `crend`
- `std::deque::iterator` is a random-access iterator

Deque - `std::deque<T, Alloc = std::allocator<T>>`

- Public methods related to capacity:
 - `size`
 - `empty`
 - `shrink_to_fit`
 - `max_size`
- In case of deque we can use comparison operators.

Deque - `std::deque<T, Alloc = std::allocator<T>>`

- How to modify deque:
 - `push_back` / `pop_back`
 - `push_front` / `pop_front`
 - `insert` / `emplace`
 - `emplace_front` / `emplace_back`
 - `resize`
 - `swap`
 - `erase`
 - `clear`

Deque - `std::deque<T, Alloc = std::allocator<T>>`

- Examples:

```
std::deque<int> l_deq{1,2,3};  
l_deq.push_back(4);  
l_deq.push_front(0);  
std::cout << "Number of elements: " << l_deq.size() << std::endl;  
std::cout << "Deque: ";  
printDeque(l_deq);  
  
l_deq.resize(2);  
std::cout << "Deque after resize: ";  
printDeque(l_deq);  
  
std::deque<int> l_deq1{1,2,3};  
std::cout << "Are deqs the same?: "<< std::boolalpha << (l_deq == l_deq1);
```

Number of elements: 5

Deque: 0 1 2 3 4

Deque after resize: 0 1

Are deqs the same?: false

Associative Containers

- Associative containers use keys to store and retrieve elements
- There are four types:
 - **std::set,**
 - **std::multiset,**
 - **std::map,**
 - **std::multimap**

Associative Containers

- All associative containers maintain keys in sorted order
- All associative containers support bidirectional iterators
- Set does not allow duplicate keys
- Multiset and multimap allow duplicate keys
- Multimap and map allow keys and values to be mapped

`std::set<Key, Comp=std::less<Key>, Alloc=std::allocator<Key>>`

- Contains sorted unique objects (does not allow duplicates)
- Elements stored inside are sorted
- Set is implemented using a red-black binary search tree for fast storage and retrieval of keys $O(\log N)$ (The complexity of search/insert/remove is logarithmic)
- The ordering of the keys is determined by the STL comparator function object `less<T>`
- Keys sorted with `less<T>` must support comparison using the `<` operator

```
template <class T, class Compare = std::less<T>, class Allocator = std::allocator<T>>  
class set;
```

```
// e.g.
```

```
std::set<int> userIds;
```

`std::set<Key, Comp=std::less<Key>, Alloc=std::allocator<Key>>`

- How to access elements:
- Using iterators:
 - `begin / cbegin`
 - `end / cend`
 - `rbegin / crbegin`
 - `rend / crend`
 - `lower_bound / upper_bound`
 - `equal_range`
 - `find`
- `std::set::iterator` and `std::multiset::iterator` are bidirectional iterators

`std::set<Key, Comp=std::less<Key>, Alloc=std::allocator<Key>>`

- Public methods related to capacity:
 - `size`
 - `empty`
 - `max_size`
 - `count`
- In case of set we can use comparison operators.

`std::set<Key, Comp=std::less<Key>, Alloc=std::allocator<Key>>`

- How to modify set:
 - insert / emplace
 - emplace_hint
 - erase
 - swap
 - clear

Set - `std::set<Key, Comp=std::less<Key>, Alloc=std::allocator<Key>>`

API	Description
<code>insert(value)</code>	This inserts a value into the set
<code>clear()</code>	This clears all the values in the set
<code>size()</code>	This returns the total number of entries present in the set
<code>empty()</code>	This will print <code>true</code> if the set is empty, and returns <code>false</code> otherwise
<code>find()</code>	This finds the element with the specified key and returns the iterator position
<code>equal_range()</code>	This returns the range of elements matching a specific key
<code>lower_bound()</code>	This returns an iterator to the first element not less than the given key
<code>upper_bound()</code>	This returns an iterator to the first element greater than the given key

- Source:
https://subscription.packtpub.com/book/application_development/9781788831390/1/ch01lvl1sec9/associative-containers

`std::set<Key, Comp=std::less<Key>, Alloc=std::allocator<Key>>`

- Examples:

```
std::set<int> l_set;  
l_set.insert(3);  
l_set.insert(122);  
l_set.insert(2);  
std::cout << "Number of elements: " << l_set.size() << std::endl;  
std::cout << "Elements: ";  
printSet(l_set);  
  
std::set<int, std::greater<int>> l_setGreater;  
l_setGreater.insert(3);  
l_setGreater.insert(122);  
l_setGreater.insert(2);  
std::cout << "Elements of l_setGreater: ";  
  
printSet(l_setGreater);  
return 0;
```

```
Number of elements: 3  
Elements: 2 3 122  
Elements of l_setGreater: 122 3 2  
|
```

Map - `std::map<Key, T, Comp=std::less<T>, Alloc=std::allocator<std::pair<const Key, T>>>`

- Allows storage and retrieval of unique key/value pairs
- Elements stored inside are sorted by unique key
- Implemented using red-black binary search trees
- Complexity of search/insert/remove methods is logarithmic
- Does not allow duplicates of keys -> Single value is stored under single key.
- The class map overloads the [] operator to access values in a flexible way

```
template <class Key, class T, class Compare = std::less<Key>, class  
Allocator = std::allocator<std::pair<const Key, T>>>  
class map;
```

```
// e.g.  
std::map<int, std::string> students;
```

Map - `std::multimap<Key, T, Comp=std::less<T>, Alloc=std::allocator<std::pair<const Key, T>>>`

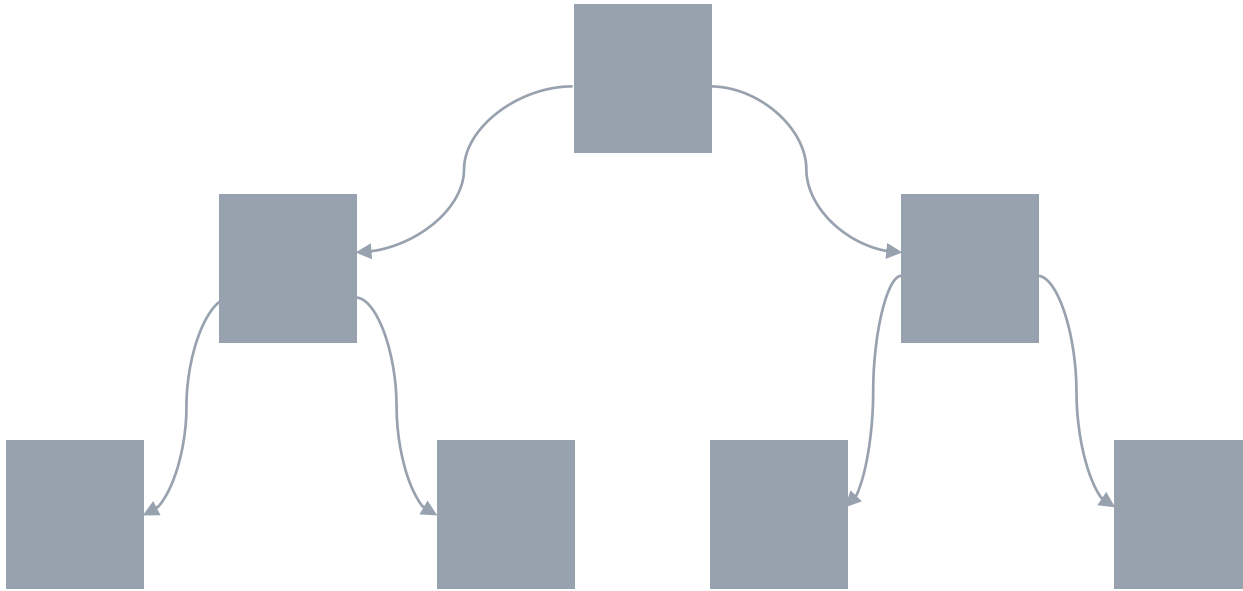

- Key-Value pairs
- Elements stored inside are sorted by key.
- Usually implemented as tree.
- Complexity of search/insert/remove methods is logarithmic.

```
template <class Key, class T, class Compare = std::less<Key>, class  
Allocator = std::allocator<std::pair<const Key, T>>>  
class multimap;
```

```
// e.g.  
std::multimap<int, std::string> students;
```

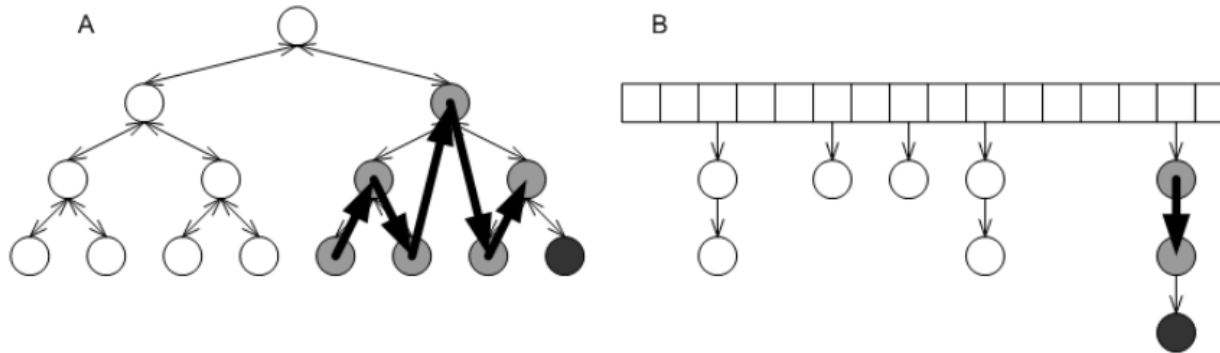

(multi)Map - `std::map<Key, T, Comp=std::less<T>, Alloc=std::allocator<std::pair<const Key, T>>>`

- How map can look (binary tree):

(multi)Map - `std::map<Key, T, Comp=std::less<T>, Alloc=std::allocator<std::pair<const Key, T>>>`

- Memory representation of multimap:
 - As per definition the binary tree is organized by keys, and they are unique for multimap
 - The role of key is to find the position of the node in the tree
 - Every node holds a value, that can be a list of variables.

Source: https://gcc.gnu.org/onlinedocs/gcc-4.7.4/libstdc++/manual/manual/policy_data_structures_design.html

Map - `std::multimap<Key, T, Comp=std::less<T>, Alloc=std::allocator<std::pair<const Key, T>>>`

- How to access elements:
 - `at` / `operator[]` (only `std::map`)
 - Using iterators:
 - `begin` / `cbegin`
 - `end` / `cend`
 - `rbegin` / `crbegin`
 - `rend` / `crend`
 - `lower_bound` / `upper_bound`
 - `equal_range`
 - `find`
- `std::map::iterator` and `std::multimap::iterator` are bidirectional iterators

Map - `std::multimap<Key, T, Comp=std::less<T>, Alloc=std::allocator<std::pair<const Key, T>>>`

- Public methods related to capacity:
 - `size`
 - `empty`
 - `max_size`
 - `count`
- In case of map we can use comparison operators.

Map - `std::multimap<Key, T, Comp=std::less<T>, Alloc=std::allocator<std::pair<const Key, T>>>`

- How to modify map:
 - insert / emplace
 - emplace_hint
 - erase
 - swap
 - clear

Map - `std::map<Key, T, Comp=std::less<T>, Alloc=std::allocator<std::pair<const Key, T>>>`

API	Description
<code>at (key)</code>	This returns the value for the corresponding key if the key is found; otherwise it throws the <code>std::out_of_range</code> exception
<code>operator[key]</code>	This updates an existing value for the corresponding key if the key is found; otherwise it will add a new entry with the respective <code>key=>value</code> supplied
<code>empty()</code>	This returns <code>true</code> if the map is empty, and <code>false</code> otherwise
<code>size()</code>	This returns the count of the <code>key=>value</code> pairs stored in the map
<code>clear()</code>	This clears the entries stored in the map
<code>count()</code>	This returns the number of elements matching the given key
<code>find()</code>	This finds the element with the specified key

- Source:
https://subscription.packtpub.com/book/application_development/9781788831390/1/ch01lvl1sec9/associative-containers

Map - `std::multimap<Key, T, Comp=std::less<T>, Alloc=std::allocator<std::pair<const Key, T>>>`

- Examples:

```
std::map<int, int> l_map = { {3, 5} };
l_map[2] = 7;
l_map[8] = 4;
l_map.insert(std::make_pair(1,2));
std::cout << "Number of elements: " << l_map.size() << std::endl;
for (const auto& it: l_map)
{
    std::cout << it.first << "->" << it.second << "\n";
}
std::cout << std::endl;

l_map[1] = 123;

for (const auto& [key, value]: l_map) // C++17
{
    std::cout << key << "->" << value << "\n";
}
```

Number of elements: 4

1->2

2->7

3->5

8->4

1->123

2->7

3->5

8->4

Map - `std::multimap<Key, T, Comp=std::less<T>, Alloc=std::allocator<std::pair<const Key, T>>>`

- Examples:

```
std::multimap<std::string, int> grades;

const std::string studentName = "Tommy";
grades.insert(std::make_pair(studentName, 5));
grades.insert(std::make_pair(studentName, 3));
grades.insert(std::make_pair(studentName, 4));

auto tommysGrades = grades.equal_range(studentName);
std::cout << "Tommy's grades: ";

for (auto itr = tommysGrades.first; itr != tommysGrades.second; itr++)
    std::cout << itr->second << ", ";
```

Tommy's grades: 5, 3, 4,

Containers::unordered_associative

- Similar to their ordered equivalents
- Unordered associative containers available in STL:
 - `std::unordered_map`
 - `std::unordered_multimap`
 - `std::unordered_set`
- Elements in the unordered containers are not sorted in any particular order but organized into buckets depending on their hash values. That allow to fast access to all elements

Containers::unordered_associative::unordered_map

- Key-Value pairs, where key is unique.
- Hash table (uses hash function to transform key into an index).
- Collision handling is needed.

```
template <class Key, class T, class Hash = std::hash<Key>, class Predicate =  
std::equal_to<Key>, class Allocator = std::allocator<std::pair<const Key, T>>>  
class unordered_map;
```

// e.g.

```
std::unordered_map<int, std::string> students;
```

Containers::unordered_associative::unordered_multimap

- Key-Value pairs, where key is unique.
- Hash table (uses hash function to transform key into an index).
- Collision handling is needed.

```
template <class Key, class T, class Hash = std::hash<Key>, class Predicate =  
std::equal_to<Key>, class Allocator = std::allocator<std::pair<const Key, T>>>  
class unordered_multimap;
```

// e.g.

```
std::unordered_multimap<int, std::string> students;
```

Containers::unordered_associative::unordered_(multi)map

- How to access elements:
 - at / operator[] (only unordered_map)
 - Using iterators:
 - begin / cbegin
 - end / cend
 - equal_range
 - find
- std::unordered_map::iterator is a forward iterator

Containers::unordered_associative::unordered_(multi)map

- Public methods related to unordered_map's capacity:
 - size
 - empty
 - max_size
 - count
- In case of unordered maps we can use only some comparison operators (!=, ==).

Containers::unordered_associative::unordered_set

- Unique values.
- Hash table (uses hash function to transform key into an index).
- Collision handling is needed.

```
template <class T, class Hash = std::hash<Key>, class Predicate = std::equal_to<Key>,  
class Allocator = std::allocator<std::pair<const Key, T>>>  
class unordered_set;
```

// e.g.

```
std::unordered_set<std::string> students;
```

Containers::unordered_associative::unordered_multiset

- Hash table (uses hash function to transform key into an index).
- Collision handling is needed.

```
template <class T, class Hash = std::hash<Key>, class Predicate = std::equal_to<Key>,  
class Allocator = std::allocator<std::pair<const Key, T>>>  
class unordered_multiset;
```

```
// e.g.  
std::unordered_multiset<std::string> students;
```

Container Adapters

- STL supports three container adapters
 - `std::stack`, `std::queue` and `std::priority_queue`
- Implemented using the containers seen before
- Do not provide new data structure
- Container adapters do not support iterators
- The functions `push` and `pop` are common to all container adapters

Stack - `std::stack<T, Container = std::deque<T>>`

- Adapts container and provides LIFO (Last in – first out) interface (elements are inserted and extracted only from the end of the container)
- Implemented with vector, list, and deque (by default)

Example of creating stacks

- A stack of int using a vector: `stack < int, vector < int > > s1;`
- A stack of int using a list: `stack < int, list < int > > s2;`
- A stack of int using a deque: `stack < int > s3;`

Stack - `std::stack<T, Container = std::deque<T>>`

- Container type has to support methods as:
 - `push_back`
 - `pop_back`
 - `back`
- Methods:
 - `top / pop`
 - `push / emplace`
 - `swap / empty / size`

Stack - `std::stack<T, Container = std::deque<T>>`

- Examples:

```
std::stack<int> l_stack;  
l_stack.push(1);  
l_stack.push(2);  
l_stack.push(3);  
std::cout << "Number of elements: " << l_stack.size()  
<< std::endl;  
  
while (!l_stack.empty())  
{  
    std::cout << l_stack.top() << " ";  
    l_stack.pop();  
}
```

```
Number of elements: 3  
3 2 1 |
```

Queue - `std::queue<T, Container = std::deque<T>>`

- First-in-first-out data structure (FIFO) (elements are inserted into one end of the container and extracted from the other)
- Implemented with a list and deque (by default)

Queue - `std::queue<T, Container = std::deque<T>>`

- Example:
 - A queue of int using a list: `queue <int, list<int>> q1;`
 - A queue of int using a deque: `queue <int> q2`
- Container type has to support methods as:
 - `push_back`
 - `pop_back`
 - `back`
- Methods:
 - `top`
 - `push / emplace / pop`
 - `swap / empty / size`

Queue - `std::queue<T, Container = std::deque<T>>`

- Example:

```
std::queue<int> l_queue;  
l_queue.push(3);  
l_queue.push(5);  
l_queue.push(1);  
std::cout << "Number of elements: " <<  
l_queue.size() << std::endl;  
  
while (!l_queue.empty())  
{  
    std::cout << l_queue.front() << " ";  
    l_queue.pop();  
}
```

```
Number of elements: 3  
3 5 1 |
```

Priority Queue - `std::priority_queue<T, Container = std::vector<T>>`

- Elements are prioritized according to comparator
- Insertions are done in a sorted order
- Deletions from front similar to a queue
- They are implemented with vector (by default) or deque
- The elements with the highest priority are removed first
 - `less<T>` is used by default for comparing elements (largest at front)

Priority Queue - `std::priority_queue<T, Container = std::vector<T>>`

- Example:

```
std::priority_queue<int> pqueue;
pqueue.push(122);
pqueue.push(2);
pqueue.push(33);
std::cout << „Number of elements: " << pqueue.size() << std::endl;

while (!pqueue.empty())
{
    std::cout << pqueue.top() << " ";
    pqueue.pop();
}
```

```
Number of elements: 3
122 33 2 |
```

Tuple - template <class... Types> class tuple;

- Structures with any number of elements of arbitrary types
- Tuples provide comparison operators, similarly as pairs
- Implemented with variadic templates
- Supports logical operators. The logical conditions are performed for every element of tuple

Tuple - template <class... Types> class tuple;

- Example:

```
auto l_tuple1 = std::make_tuple(1, 2.3, "Lukasz");
std::tuple<int, double, std::string> l_tuple2(1, 3.14, "PI");

std::size_t s = std::tuple_size<decltype(l_tuple1)>::value;
std::cout << "Size: " << s << std::endl;

std::cout << "Tuple1: " <<
    std::get<0>(l_tuple1) << ", " <<
    std::get<1>(l_tuple1) << ", " <<
    std::get<2>(l_tuple1) << std::endl;

std::tuple<int, float, char*> l_tuple3(1, 2.0f, nullptr);
std::get<2>(l_tuple3) = new char[13];

// C++17
std::tuple l_tuple4{ 2, 6.28, "2*PI" };
auto [index, value, name] = l_tuple4;
std::cout << "Tuple4: " << index << ", " << value << ", " << name << std::endl;
std::cout << "Is tuple1 the same as tuple2?: " << std::boolalpha << (l_tuple1 == l_tuple2);
```

```
Size: 3
Tuple1: 1, 2.3, Lukasz
Tuple4: 2, 6.28, 2*PI
Is tuple1 the same as tuple2?: false
```

std::string

- std::string class is a container for raw strings
- Provides an interface that simplify working with strings

```
const char* rawString = „PK“;
std::string stdString = rawString;

std::cout << "Raw: " << rawString << std::endl;
std::cout << "STD: " << stdString << std::endl;
stdString += " is great"; // append string
std::cout << "Raw: " << rawString << std::endl;
std::cout << "STD: " << stdString << std::endl;
std::cout << "POS_GREAT: " << stdString.find("great") << std::endl;
std::cout << "POS_BORING: " << (int)stdString.find("boring") << std::endl;
std::cout << "Length: " << stdString.length() << std::endl;
```

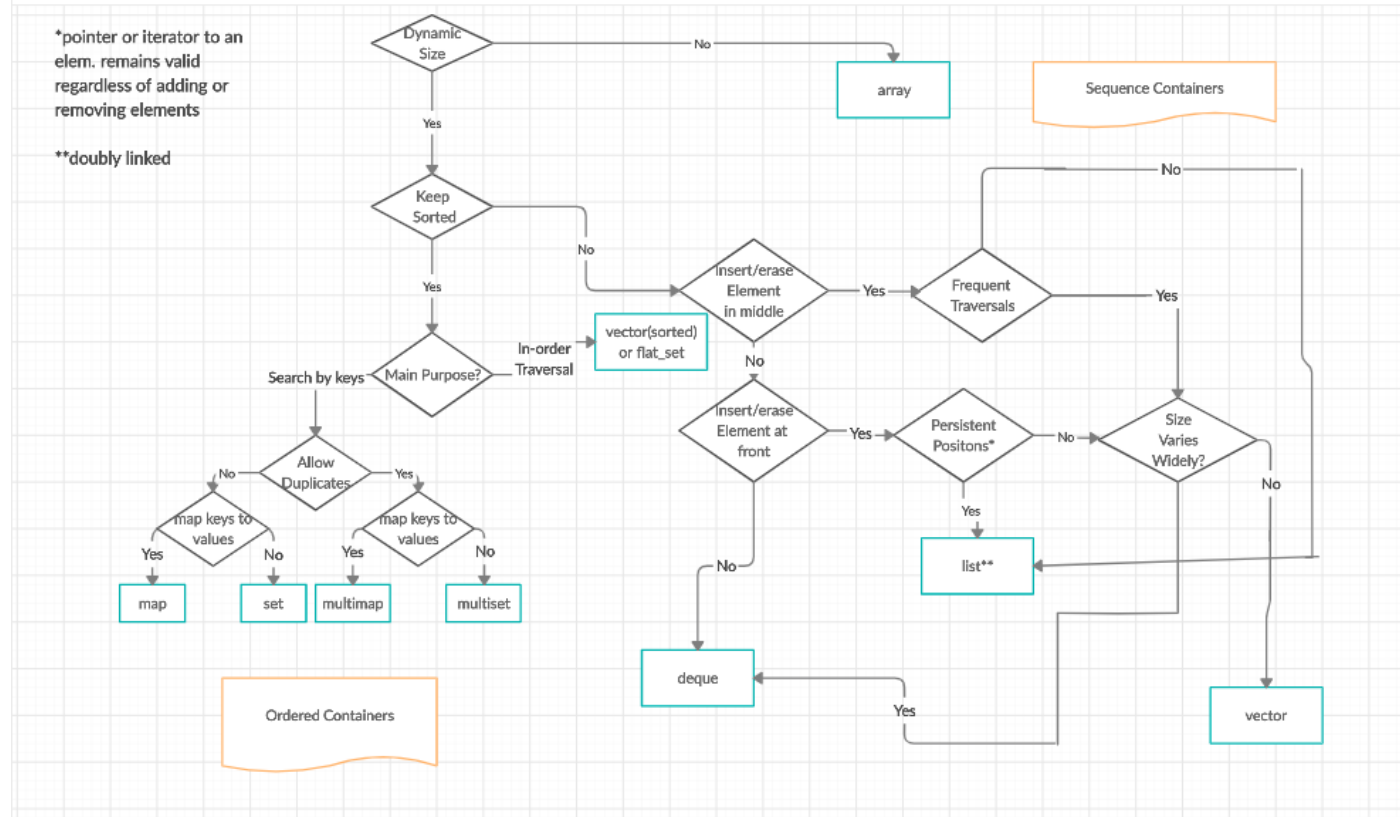

Sequence vs Associative

- Sequence containers:
 - Element access: constant time $O(1)$
 - Simple inserting: $O(n)$ vector/deque, $O(1)$ list
 - Inserting at Front: constant time $O(1)$ (amortized) / $O(n)$ worst case
 - Inserting at End: $O(1)$ (more complex in case of reallocation)
 - Inserting in the middle: quite slow
- Associative containers (most complexities are in logarithmic terms)
 - Inserting an element: $O(\log n)$
 - Insertion in middle is faster than in Sequence containers
 - Removing an element: $O(\log n)$
 - Looking for an element: $O(\log n)$
 - Incrementing or decrementing iterator: $O(1)$ (amortized)

Sequence vs Associative

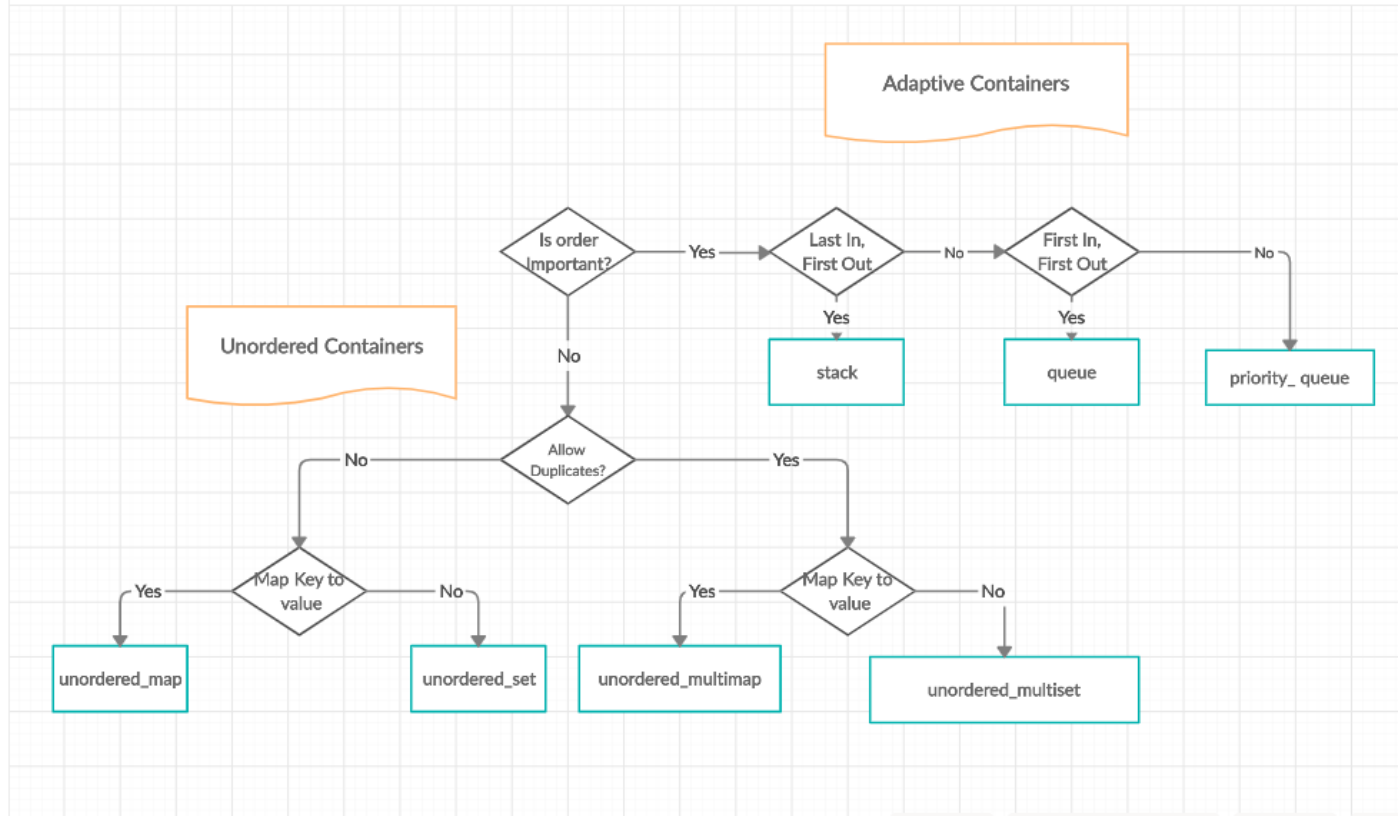

- Sequence containers:
 - Simple inserting: constant time $O(1)$
 - Inserting at Front: constant time $O(1)$ (amortized)
 - Inserting in the middle: quite slow
- Associative containers (most complexities are in logarithmic terms)
 - Inserting an element: $O(\log n)$
 - Insertion in middle is faster than in Sequence containers
 - Removing an element: $O(\log n)$
 - Looking for an element: $O(\log n)$
 - Incrementing or decrementing iterator: $O(1)$ (amortized)

When to use:

When to use: Adaptive Containers

Source: [geeksforgeeks.com](https://www.geeksforgeeks.com)

Summary:

		array	vector	deque	forward list	list	set	map	unordered set	unordered map
Properties	Fixed size	YES	-	-	-	-	-	-	-	-
	Sequence	YES	YES	YES	YES	YES	-	-	-	-
	Contiguous storage	YES	YES	-	-	-	-	-	-	-
	Associative	-	-	-	-	-	YES	YES	YES	YES
	Ordered	-	-	-	-	-	by unique key=value	by unique key	*	*
Element access	operator[], at	O(1)	O(1)	O(1)	-	-	-	O(log N)	-	O(1)**
	front	O(1)	O(1)	O(1)	O(1)	O(1)	-	-	-	-
	back	O(1)	O(1)	O(1)	-	O(1)	-	-	-	-
	find	-	-	-	-	-	O(log N)	O(log N)	O(log N)	O(log N)
Modi- fiers	insert	-	O(n)	O(n)	O(1)	O(1)	O(log N)	O(log N)	O(log N)	O(log N)
	push_front	-	-	O(1)***	O(1)	O(1)	-	-	-	-
	push_back	-	O(1)***	O(1)***	-	O(1)	-	-	-	-

* - not sorted in any particular order, but organized into buckets depending on their hash values

** - average case: constant – O(1), worst case: linear in size – O(n).

*** - more complex when reallocation needed

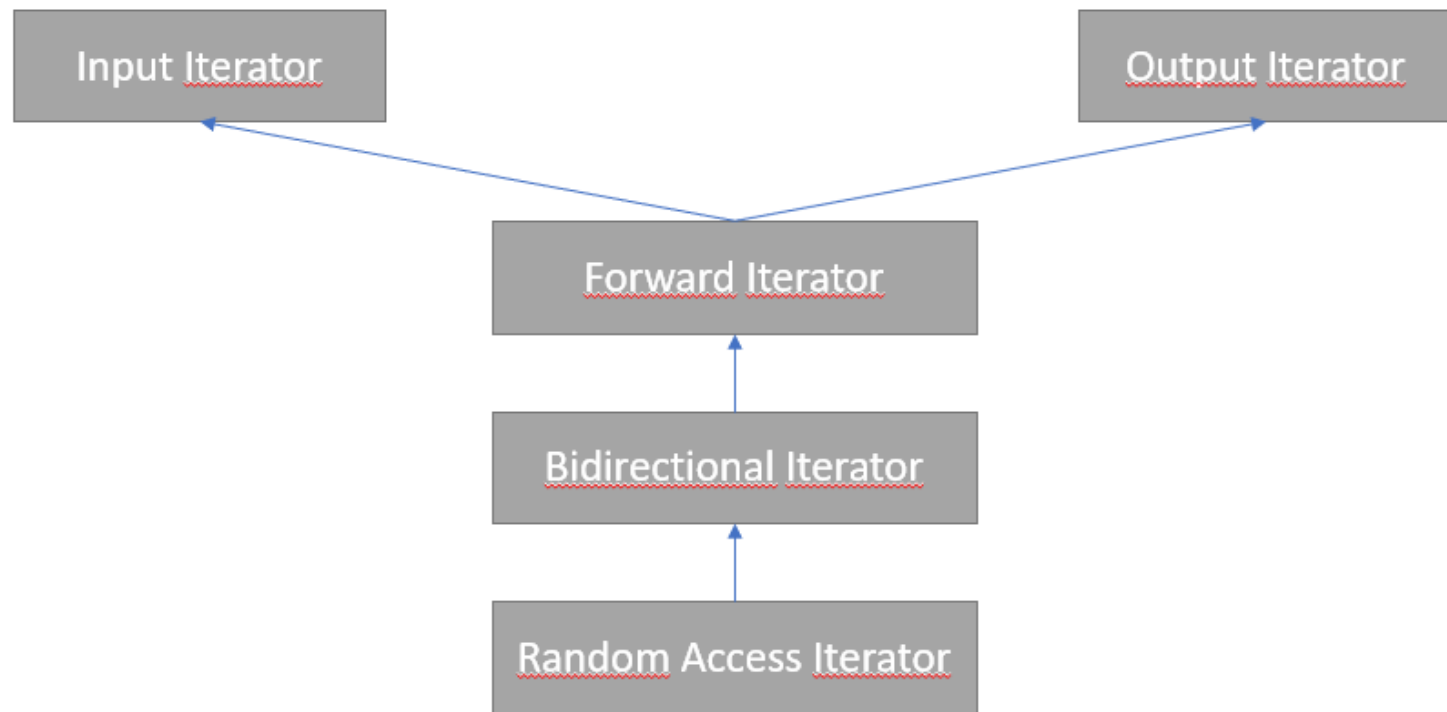

Iterators

- Type that can be used to identify and traverse the elements of a container.
- Container provides iterator. Iterator does not know about container type it originates from
- All first-class containers provide the members functions `begin()` and `end()`
 - returns iterators pointing to the first and one-past-the-last element of the container
- Iterators are pointers to elements of first-class containers:
 - Type `const_iterator` defines an iterator to a container element that cannot be modified
 - Type `iterator` defines an iterator to a container element that can be modified
 - `cbegin()`, `cend()`, `crbegin()`, `crend()` – return always `const` iterators, even on non-`const` objects
 - Iterators have „asterisk” operator – „`*iter`” is valid expression
 - Iterators have „arrow” operator – „`iter->`” is valid expression

Iterators

- If the iterator it points to a particular element:
 - **it++ (or ++it)** points to the next element and
 - ***it** refers to the value of the element pointed to by **it**
 - **== and !=** check if two iterators represent the same position
 - **=** assigns an iterator

Iterators

Iterators

Iterator category					Defined operations
ContiguousIterator	RandomAccessIterator	BidirectionalIterator	ForwardIterator	InputIterator	<ul style="list-style-type: none">• read• increment (without multiple passes)
					<ul style="list-style-type: none">• increment (with multiple passes)
					<ul style="list-style-type: none">• decrement
					<ul style="list-style-type: none">• random access
					<ul style="list-style-type: none">• contiguous storage

Iterators::types::InputIterator

- LegacyInputIterators only guarantee validity for single pass algorithms: once LegacyInputIterator has been incremented, all copies of its previous value may be invalidated.

<u>InputIterator</u>	<ul style="list-style-type: none">• read• increment (without multiple passes)
----------------------	--

Example: reading input

Iterators::types::InputIterator

```
#include <iostream>
#include <iterator>

int main()
{
    std::istream_iterator<int> input(std::cin);
    std::copy(input, {}, std::ostream_iterator<int>(std::cout, ", "));

    return 0;
}
```

Iterators::types::ForwardIterator

- Uses only ++ for passing through containers one element at a time
- Permits values to be accessed and modified

<u>ForwardIterator</u>	<ul style="list-style-type: none">• read• increment (without multiple passes)
	<ul style="list-style-type: none">• increment (with multiple passes)

Example: iterating over singly-linked list

Iterators::types::ForwardIterator

```
#include <iostream>
#include <forward_list>
#include <iterator>
```

```
std::forward_list<int> l{1, 2, 3, 4, 5};
std::copy(l.begin(), l.end(), std::ostream_iterator<int>(std::cout, ", "));
```

```
std::cout << "\nSquares: ";
for (auto it = l.begin(); it != l.end(); ++it)
{
    *it = (*it) * (*it);
    std::cout << *it << " ";
}
```

```
return 0;
```

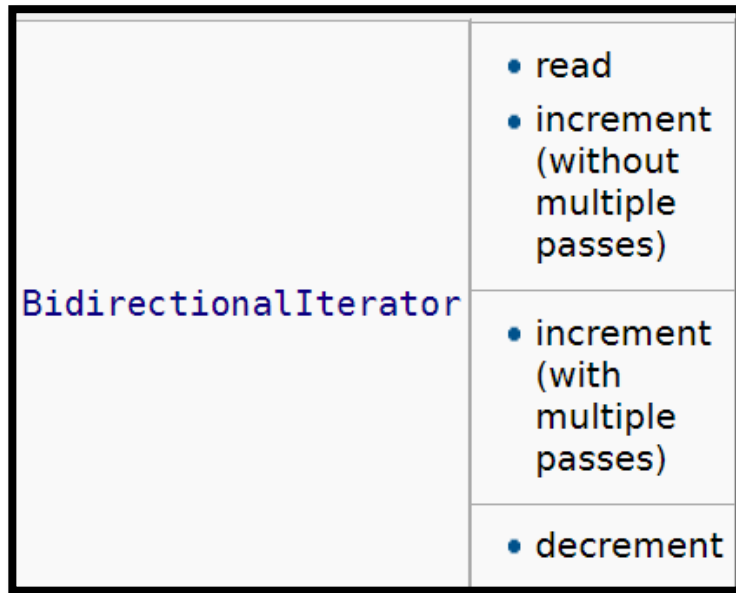

```
1, 2, 3, 4, 5,
Squares: 1 4 9 16 25
```

  https://en.cppreference.com/w/cpp/container/forward_list

const_pointer	<code>std::allocator_traits<Allocator>::const_pointer</code>
iterator	<i>LegacyForwardIterator</i>
const_iterator	Constant <i>LegacyForwardIterator</i>

Iterators::types::BidirectionalIterator

- Extends forward iterator with a support for decrement operators (prefix and postfix)

Example: iterating over doubly-linked list

Iterators::types::BidirectionalIterator

```
#include <iostream>
#include <list>
#include <iterator>

int main()
{
    std::list<int> l{1, 2, 3, 4, 5};
    for (auto itF = l.begin(); itF!=l.end(); ++itF)
    {
        std::cout << *itF << " ";
    }

    std::cout << std::endl;

    for (auto itR = l.end(); itR!= l.begin(); )
    {
        --itR;
        std::cout << *itR << " ";
    }

    return 0;
}
```

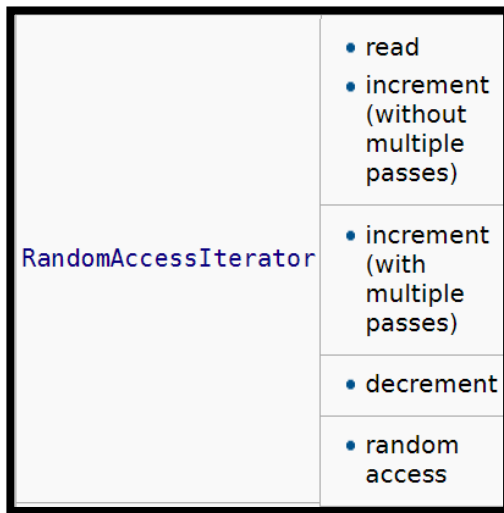

1 2 3 4 5
5 4 3 2 1

  <https://en.cppreference.com/w/cpp/container/list>

const_pointer	<code>std::allocator_traits<Allocator>::</code>
iterator	<code>LegacyBidirectionalIterator</code>
const_iterator	Constant <code>LegacyBidirectionalIterator</code>

Iterators::types::RandomAccessIterator

- Extends bidirectional iterator with the operations such as pointer addition and relational operations
- Used by multi-pass algorithms

Example: iterating over vector

Iterators::types::RandomAccessIterator

```
std::vector<int> v1 = {1, 2, 3, 4, 5};
std::vector<int>::iterator it1;
it1 = v1.begin();
auto it2 = v1.end();

std::cout << "Relational operator:\n";
if (it1 < it2)
{
    std::cout << "Yes";
}

std::cout << "\nArithmetic operator:";
int count = it2 - it1;
std::cout << "\nCount = " << count;

it2 = v1.end() - 3;
std::cout << "\n" << *it2 << "\n";

std::cout << "\nDereferncing:";
*it2 = 153;
for (const auto& it: v1)
{
    std::cout << it << " ";
}
```

Relational operator:

Yes

Arithmetic operator:

Count = 5

3

Dereferencing:1 2 153 4 5

Iterators::types:: OutputIterator

- Output iterators allow to modify associated sequence
- Opposite to an input iterator, however dereferencing allows midification but not reading of an element
- Single-pass and write-only iterator
- Examples with containers:
 - `insert_iterator` – calls `insert()`
 - `back_insert_iterator` – calls `push_back()`
 - `front_insert_iterator` – calls `push_front()`
- Example with streams:
 - `ostream_iterator` – writes to given ostream using `operator<<`

OutputIterator

- **write**
- **increment**
(without
multiple
passes)

Iterators::types:: OutputIterator

```
#include<iostream>
#include<vector>
#include<deque>
#include<forward_list>
#include<iterator>

int main()
{
    std::deque<int> deque = {6, 11, 12, 13, 14};
    std::copy(deque.begin(), deque.end(), std::ostream_iterator<int>(std::cout, " | "));
    std::cout << std::endl;

    std::forward_list<int> list {7, 8, 9, 10};
    std::copy(list.begin(), list.end(), std::inserter(deque, std::next(deque.begin())));
    std::copy(deque.begin(), deque.end(), std::ostream_iterator<int>(std::cout, " | "));
    std::cout << std::endl;

    std::vector<int> vec {5, 4, 3, 2, 1};
    std::copy(vec.begin(), vec.end(), std::front_inserter(deque));
    std::copy(deque.begin(), deque.end(), std::ostream_iterator<int>(std::cout, " | "));
    std::cout << std::endl;

    return 0;
}
```

```
6 | 11 | 12 | 13 | 14 |
6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 |
1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 |
```

Iterators::operations

advance

advances an iterator by given distance
(function template)

distance

returns the distance between two iterators
(function template)

next
(C++11)

increment an iterator
(function template)

prev
(C++11)

decrement an iterator
(function template)

R-value references

- Avoid unnecessary copying of temporary values
- Efficient objects like `std::vector<std::string>`
- Move constructors and move assignment operators defined similarly as typical constructors and assignment operators, but using `&&` (r-value reference)

```
class C {  
    C(const C& rhv);  
    C(C&& rhv);  
    C& operator=(const C& rhv);  
    C& operator=(C&& rhv);  
    ...  
};
```

typically both move and copy semantic should be defined

R-value reference can be used in normal functions as well
they can be overloaded, `T&` and `T&&` are distinct types

Move semantic

- Move constructors and move assignment operators can *steal* data from its arguments
- Formally, after move the arguments may remain in unspecified state, but the state still has to be valid
- No further functions can be called on these objects
 - such functions would cause unspecified results
- However, destructors are always executed

Typical implementation of move constructor

```
C(C&& rhv)
{
    ptr_data = rhv.ptr_data; // data stealing
    rhv.ptr_data = nullptr; // the state of rhv
                             // must remain valid
}
~C() { delete[] ptr_data; } // safe even after move
```

Using move

Compiler decides when move semantic is used

```
C obj1;           // always copy semantic,  
C obj2(obj1);     // obj1 still can be used  
  
C func(int x);    // move semantic (if defined)  
C o3(func(0));    // result of func cannot be used anymore
```

The move semantic can be forced using `std::move` from `<utility>` header

```
C obj2(std::move(obj1)); // force move semantic
```

now it is programmer responsibility not to use `obj1`, since it is in unspecified state

however, the new value can be safely assigned to `obj1`

the destructor for `obj1` will be called automatically

The `std::move` utility function is overload to ranges of objects (using iterators)

Constant expressions

- May be used to mark constants and functions
- Keyword `constexpr` guarantees that a constant initializer is evaluated to a compile-time constant, or causes a compile error if this is not possible
- Functions marked as `constexpr`
 - can have only a single `return` statement
 - can depend only on its arguments and globals marked as `constexpr`
 - can call only `constexpr` functions

In C++14 these requirements were relaxed, allowing:

- branches and loops (without `goto`)
- automatic (non-static) variables
- calling non-const functions on objects with lifetime limited to the `constexpr` function

Constant expressions

Example:

```
constexpr int const1 = 1;    // OK
int const2 = 2;

constexpr int func(int x) {
    return x*x + const1; }    // OK
constexpr int func2(int x) {
    return x*x + const2; }    // compile error

template<int N, int M> class Matrix {...};
Matrix<func(1), func(2)> m;    // OK

int i = 3;
int j = func(i);              // OK, j is non-constexpr
constexpr int k = func(i);    // compile error
```

- Numeric limits are redefined to be constexpr

```
Matrix<std::numeric_limits<short>::max(),
      std::numeric_limits<short>::max()> m; // OK in C++11
```

Less errors

Less error prone code by detecting more errors at compile time

Nullptr (1/2)

The numeric constant 0 is used as both an integer and a pointer

```
int i = 0;
void* ptr = 0;
```

Not really a problem in C

The following macros are used for better code readability

```
#define NULL (void*)0 // in C
#define NULL 0        // in C++
```

Does not work with function overloading

```
void f(int i);
void f(char* ptr);
f(NULL); // probably an error, calls int version!
```

Does not provide type control

```
ptr = NULL; // OK
i = NULL;   // also OK
```

Nullptr (2/2)

But from C++11 onwards:

```
f(nullptr);    // calls char* version  
ptr = nullptr; // OK  
i = nullptr;   // compile error
```

The `nullptr` expression evaluates to a distinct type value that can be implicitly casted to any *pointer* (but not to an integer)

The type of `nullptr` is *NOT* `void*`

`std::nullptr_t`, defined as

```
typedef decltype(nullptr) nullptr_t;
```

Can be explicitly overloaded

```
f(void* ptr);           f(std::nullptr_t ptr);  
f(char* ptr);           f(char* ptr);  
f(nullptr); // compile error  f(nullptr); // OK  
              // ambiguity
```

Override specifier

Virtual functions in C++03 are prone to errors

```
class Base {  
    virtual void func(double x);  
};  
  
class Derived: public Base {  
    void func(float x); // probably an error  
};  
  
Base* obj = new Derived();  
obj->func(1); // compiles OK, but calls Base::func
```

But from C++11 onwards compiler can detect such errors

```
class Derived1: public Base {  
    void func(float x) override; // compile error  
};  
  
class Derived2: public Base {  
    void func(double x) override; // OK  
};
```

Final

Classes and member functions can be marked as `final`

```
class Cf final {...};  
class Base {  
    virtual void func();  
};  
class Derived: public Base {  
    void func() final;  
};
```

If `final` is used, some constructions cause compile errors

```
class Derived1: public Cf {...};           // compile error  
class Derived2: public Derived {...};      // OK  
class Derived3: public Derived {  
    void func(); // compile error  
};
```

Default / Deleted

Constructors and assignment operators can now be explicitly specified as `default` or `deleted`

```
class C1 {  
    C1(const C1& rhv) = default;  
};  
  
class C2 {  
    C2(const C2& rhv) = deleted;  
    C2& operator=(const C2& rhv) = deleted;  
};
```

Objects of type C1 are explicitly specified to be copied with default copy constructor

Objects of type C2 explicitly cannot be copied

no more need for undefined c'tors in private sections

Any function, as well as function template, can be marked as `deleted`

For each

The C++11 provides new alternative syntax for the `for` loop:

```
int data[4] = {1, 2, 3, 4};  
for (int& x: data)  
    std::cout << x << " ";
```

the loop operates on the entire range of data

counter handling and termination condition is managed automatically

Global `std::begin()` and `std::end()` have to be defined for any data range that is used in such a loop

standard library defines these functions for arrays in `<iterator>` header

similar template functions are also defined for containers which define `begin()` and `end()` as member functions

Static asserts

Asserts which are tested during compile time

Useful for quick detection of errors, especially within templates and constant expressions
(constexpr)

Example:

```
template<class T>
class Flags {
    static_assert(sizeof(T) >= sizeof(int),
        "Provided type is too small");
    T data;
};

Flags<char> f1; // compile error
Flags<long> f2; // OK
```

If an assertion fails, a `static_assert` causes a compile error, using given string in an error message
